

Azure AZ-104 Lab Summary

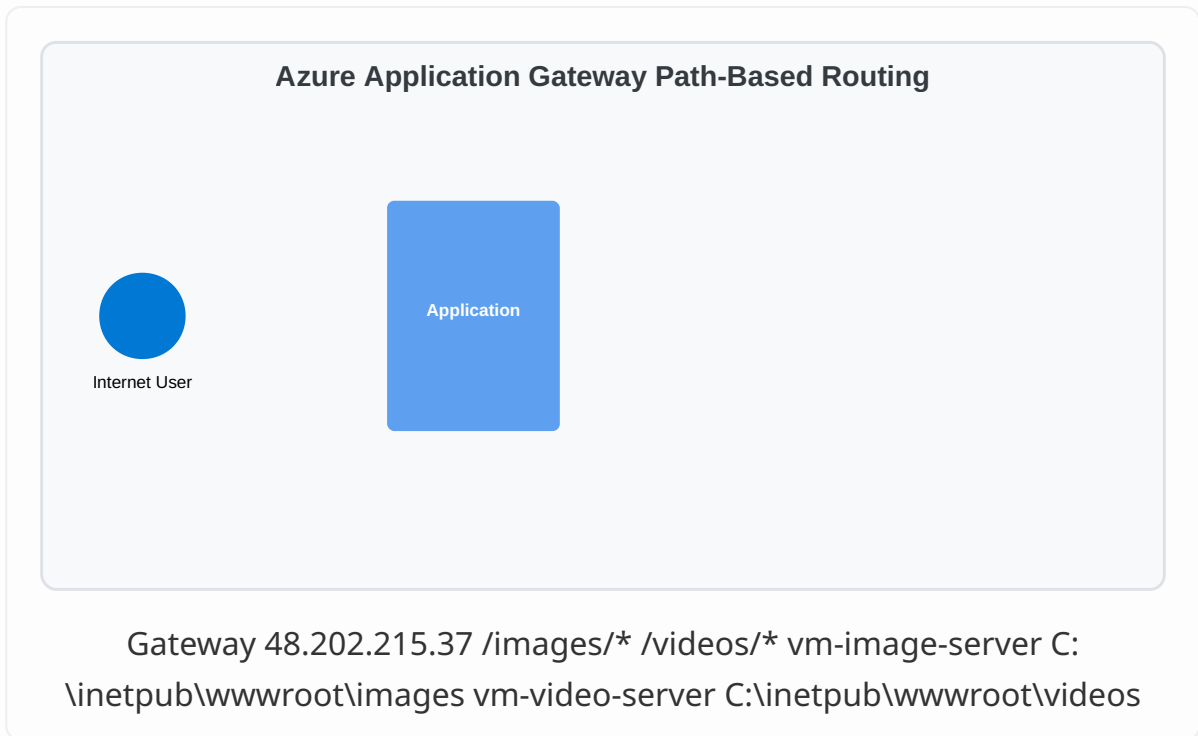

Traffic Management: Application Gateway Path-Based Routing

LAB VERIFIED: SUCCESS

Key Exam Takeaways

- **Listener-Rule Binding:** A Listener and Rule have a strict 1:1 relationship. To switch from 'Basic' to 'Path-Based' in the portal, the existing rule must often be replaced or a secondary dummy rule used to free the listener.
- **Layer 7 Awareness:** Unlike standard Load Balancers, Application Gateway inspects the URI string to make routing decisions.
- **Directory Mapping:** The backend IIS server must physically contain folders matching the URL path (e.g., /images/) or it will return a 404 error even if routing is correct.

Architecture Topology

Implementation Summary

The lab involved deploying a regional Application Gateway to route traffic to two distinct backend pools based on URI paths. Key technical challenges included overcoming the Azure Portal's UI lock on existing routing rules and configuring IIS folder structures via PowerShell.

Verified Test Endpoints:

- `http://48.202.215.37/images/index.html` → **Image Pool**
- `http://48.202.215.37/videos/index.html` → **Video Pool**

Deployment Command (PowerShell)

```
# Ensure folder matches URL path
New-Item -Path "C:\inetpub\wwwroot\images" -ItemType Directory -Force
"<h1>Success: Images Backend</h1>" | Out-File -FilePath "C:
\inetpub\wwwroot\images\index.html"
```
